

MY FIRST WEBSITE TOOLBOX

HTML + CSS quick reference - find the tool you need and use it

You do not need to memorize everything. Know what the tools do and where to find them.

HTML - What Goes on the Page?

<html> Container around the whole page.	<head> Browser information, usually not visible.	<title> Text on the browser tab.
<style> Write CSS inside the HTML file.	<body> Everything visible on the page.	<h1>...<h6> Headings. h1 is most important.
<p> Paragraph text.	
 New line.	<button> Clickable button.
 Link. href = where it goes.	 Image. src = where it comes from.	<div> General-purpose box.

Named website boxes

<header> Top/header box.	<nav> Box for navigation links.	<main> Main page-content box.	<section> Box for one topic/section.
<footer> Bottom/footer box.	class Reusable name for CSS.	id Name for one special element.	Think: header/nav/main/section/footer are meaningful boxes, similar to div.

CSS 1 - Make It Look Good

color Text colour.	background-color Background colour.	width Width.	height Height.
font-size Text size.	font-family Font.	font-weight Normal / bold.	text-align Left / center / right.
border-width Border thickness.	border-style Usually solid.	border-color Border colour.	border-radius Rounded corners.

Selectors

h1 { } Style every h1.	.card { } Style every element with class="card".	#score { } Style the element with id="score".
----------------------------------	--	---

CSS 2 - Space + Website Skills

padding Space inside the element.	margin Space outside the element.	-top / -right / -bottom / -left Change one side only.
margin: auto Center a box that has a width.	margin: 0 Remove margin, often from body.	width: 80% Percentage of available width.
text-align: center Center text/content inside.	text-decoration: none Remove link underline.	cursor: pointer Hand cursor for clickable items.

```
padding: 10px 20px 30px 40px; /* top, right, bottom, left */
margin: 20px auto;           /* vertical space + centered box */
```

Memory: Padding = inside. Margin = outside. `margin: auto` centers the box. `text-align: center` centers what is inside.

CSS 3 POWER TOOLS

Useful layout skills for better websites and simple games

Display

display: block

Own line. div is block by default.

display: inline

Stays in the line with text.

display: inline-block

Sits beside others but can have width/height.

display: none

Completely hides an element.

Flexbox - Easy Rows and Columns

display: flex

Turn a box into a flex layout.

gap

Space between flex items.

flex-direction

row = side by side; column = top to bottom.

justify-content

Move items along the main direction.

align-items

Line items up across the other direction.

flex-wrap: wrap

Move items to a new row when needed.

```
.cards { display: flex; gap: 20px; justify-content: center; flex-wrap: wrap; }
```

Position - Move Things Precisely

static

Normal/default flow. The element stays where HTML naturally puts it.

relative

Starts in its normal place, then `left/top/right/bottom` shift it relative to that place.

absolute

Leaves normal flow and uses exact coordinates. Usually measured from a positioned parent.

```
.box { position: relative; left: 30px; top: 10px; }  
.player { position: absolute; left: 50px; top: 200px; }
```

3-line position review: `static` = normal place. `relative` = normal place + shift. `absolute` = exact coordinates outside normal flow.

Coordinates

left

Distance from the left.

top

Distance from the top.

right

Distance from the right.

bottom

Distance from the bottom.

One Useful Extra

overflow: hidden

Hide anything that sticks outside a box. Useful for game areas and image cards.

Mini Website Shape

```
<header>...</header>  
<nav>...</nav>  
<main>  
  <section class="card">...</section>  
</main>  
<footer>...</footer>
```

For today: Build with normal HTML flow first. Use Flexbox when you want a row/column layout. Use `position` when something really needs to move or sit at exact coordinates.

RBS Code - My First Website Toolbox - Build first. Look things up when you need them.
